## CLAIMS

1. In a computing device having a processor that generates a first address signal of a first width and one or more peripheral devices that are addressed with a second address signal of a second width that is greater than the first width, wherein the second address signal is produced in the computing device by concatenating an address extension from an address extension register with the first address signal, a method comprising:

concurrently executing threads of a plurality of application programs, wherein different ones of the threads indicate one or more address extensions to an operating system;

storing the address extensions for use by the operating system;

repeatedly switching between execution of the threads; and

prior to executing a particular thread, writing the address extension of the base address indicated by the particular thread to the extension register.

2. A method as recited in claim 1, wherein the address extensions are indicated as a value of the second width.

3. A method as recited in claim 1, wherein individual address extensions identify address ranges associated with one or more peripheral devices.

4. A method as recited in claim 1, further comprising calling an operating system device driver from one of the threads, wherein the device driver invokes an initialization function to indicate the one or more base addresses.

14. A multi-tasking operating system as recited in claim 12, wherein each address extension identifies an address range associated with one or more peripheral devices.

15. One or more computer-readable storage media containing a multi-tasking operating system as recited in claim 12.

16. A computing device comprising:  
a processor that generates a first address signal having a first width;  
one or more peripheral devices that are addressed with a second address signal having a second width that is greater than the first width;  
an address extension register that stores an address extension, wherein the address extension is combined with the first address signal to create the second address signal; and  
the processor being programmed to record the address extension being used by a first execution thread, to interrupt the first execution thread to execute portions of one or more other execution threads, to restore the recorded address extension to the address extension register after executing said portions of one or more other execution threads, and to resume the first execution thread after restoring the recorded address extension to the address extension register.

17. A computing device as recited in claim 16 wherein each address extension identifies an address range associated with one or more peripheral devices.

18. A computing device as recited in claim 16 wherein the processor is further programmed to record and restore address extension for a plurality of execution threads.

19. A computing device as recited in claim 16 wherein the processor is programmed to perform the following steps upon interrupting the first execution thread to begin execution of the one or more other execution threads:

recording the address extension being used by the one or more other execution threads; and

interrupting the one or more other execution threads to resume the first execution thread.

20. A computing device comprising:  
a processor that generates a first address signal having a first width;  
one or more peripheral devices that are addressed with a second address signal having a second width that is greater than the first width;  
an address extension register that stores an address extension, wherein the address extension is combined with the first address signal to create the second address signal;  
a multi-tasking operating system that switches between execution of different application programs;  
a plurality of application programs that use different address extensions, wherein execution threads of the application programs register one or more such address extensions with the multi-tasking operating system;

Sub  
A1

6602991019 MS1-317US.PAT.APP.DOC

1 wherein the operating system records the registered address extensions and  
2 automatically writes an address extension of a particular application program  
3 thread to the address extension register before switching to execution of said  
4 particular application program thread.

5  
6 **21.** A computing device as recited in claim 20, wherein each address  
7 extension identifies an address range associated with one or more peripheral  
8 devices.

9  
10 **22.** A computing device as recited in claim 20, wherein operating  
11 system records the registered address extensions in a memory table.

12  
13 **23.** A computing device as recited in claim 20, wherein the execution  
14 threads of the application programs invoke operating system device drivers, the  
15 operating system device drivers registering said one or more address extensions  
16 with the multi-tasking operating system.

17  
18 **24.** A computer program stored in a storage medium, comprising:  
19 instructions for performing read/write operations on a peripheral device,  
20 wherein loading an extension register is a predicate to performing said read/write  
21 operations; and

22 instructions for providing one or more address extension values to a multi-  
23 tasking operating system for use with one or more threads of the computer  
24 program, wherein the operating system automatically loads said one or more

28. A computer program as recited in claim 26, further comprising a step of alternately executing more than one execution thread.

29. A computer program as recited in claim 28, further comprising a step of storing more than one address extension value in memory, each value being associated with a particular execution thread.

30. A computer program as recited in claim 28, further comprising:  
storing more than one address extension value in memory, each value being associated with a particular execution thread; and  
loading the extension register with the value in memory associated with a particular execution thread prior to resuming execution of that execution thread.

31. A computer program as recited in claim 28, further comprising:  
storing more than one address extension value in memory, each value being associated with a particular execution thread; and  
loading the extension register with the value in memory associated with a particular execution thread prior to resuming execution of that execution thread;  
wherein each address extension identifies an address range associated with one or more peripheral devices.

32. A computer program as recited in claim 28, wherein the computer program executes an operating system device driver from an interruptible execution thread of the program wherein said device driver identifies a peripheral device to be accessed by the execution thread and identifies a value associated with the execution thread.
